# Image filtering using MMX technology 

Report about motivation article
vasko.anton@gmail.com

## Content

n Brief overview of MMX technology
n Sample assignment
n MMX optimization of filtering
n Conclusion

## MMX - data types

4 new data types (64 bits wide)

1. packed byte
2. packed word
3. packed doubleword
4. quadword

## MMX - registers

n 8 new registers MM0 - MM7, 64 bits wide
n physically mirrored in FP stack

## MMX - instructions

57 new instructions:

1. arithmetic (padd, psub, pmul ...)
2. comparison (pcmpeq, pcmpgt)
3. conversion (pack,punpck)
4. logical (pand, pandn, por, pxor)
5. shift (psll, psrl, psra)
6. data transfer (movq, movd)
7. state management (emms)

## Reasons for MMX optimization analysis

n Image filtering is computational expensive (e.g. for picture of size 256x256 and separable $3 \times 3$ filter 256 * 256 * $(3+3)=$ 393216 multiplication is needed)
n Often used in multimedia
n MMX = MultiMedia eXtension
n Is image filtering suitable candidate for MMX optimization?

## Sample assignment

n 2D image with 8-bit color values
n $3 \times 3$ separable filter kernel
n Filter coefficient are signed 8 bit with sum of 64 - normalization is shifting (instead of divide)

## Basic Strategy

n MMX multiplying is on packed words (16-bits) =>

1. Read 8-bit pixels
2. Unpack them to 16 -bits
3. Multiply by the filter coefficients (already preformatted into 16-bit data)
4. Sum products
5. Produce normalized result using arithmetic right shift
6. Convert back from word to byte format

## Filter operations

n Filter operations:

n 2 steps - horizontal and vertical filtering
n Let start with the vertical one, because it is easier and fits very nicely the parallelism of the MMX instructions

## Vertical filter strategy

$$
\begin{aligned}
\text { n }\left[y 0^{\prime}, y 1^{\prime}, \mathrm{y} 2^{\prime}, \mathrm{y} 3^{\prime}\right]= & {[\mathrm{x} 0, \mathrm{x} 1, \mathrm{x} 2, \mathrm{x} 3]^{*} \mathrm{v} 0+} \\
& {[y 0, \mathrm{y} 1, \mathrm{y} 2, \mathrm{y} 3]^{*} \mathrm{v} 1+} \\
& {[\mathrm{z} 0, \mathrm{z} 1, \mathrm{z}, \mathrm{z} 3]^{*} \mathrm{v} 2 }
\end{aligned}
$$

|  |  |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | x0 | x1 | $\times 2$ |  | $\times 3$ | $\times 4$ | $\times 5$ | $\times 6$ |  | x 7 |
|  | y0 | y1 | y2 |  | y | y 4 | y5 | y6 |  | 7 |
|  | z0 | z1 | z2 |  | 23 | $z 4$ | z5 | $z 6$ |  | 27 |
|  |  |  |  |  |  |  |  |  |  |  |
|  | Image plane |  |  |  |  |  |  |  |  |  |

## Unscheduled code

```
; Vertical pass of a 3\times3 separable image filter
; Assume:
; esi points to line of X's
; edi points to output line (the line before X's
; edx contains the line-to-line "stride"
; memv0 is the memory location containing [v0,v0,v0,v0] (16 bit values)
; memv1 is the memory location containing [v1,v1,v1,v1] (16 bit values)
; mm6 contains zero
mm7 contains [v2,v2,v2,v2] (16 bit values)
; This code does the four low-order pixels in a group of eight.
; To do the high-order pixels use the same code with punpckhbw
; instead of punpcklbw
;
mova mom0, [esi] ; Load X's
punpcklbw
pmullw
movg
punpcklbw
pmullw
movg
punpcklbw
pmullw
paddsw
paddsw
psraw
packuswb
movd
mm0, mum6
; Unpack with zeros to get words
mm0, memv0 ; Multiply by v0
mm1, [esi + edx] ; Load Y's
mm1, mm6 ; Unpack with zeros to get words
mm1, memv1 ; Multiply by v1
mm2, [esi + 2* edx] ; Load Z's
mm2, mm6 ; Unpack with zeros to get words
mm2, mm7 ; Multiply with v1
mm0, rm1 ; Accumulate
mm0, mam2 ; Finish accumulation
mm0,6 ; Normalize
mm0, mom0 ; Pack into four low-order bytes
[edi], mom0 ; Write result into memory
```

## Improvements

n Resources analyze - 1 register for unpacking, 3 registers for 3 image lines =>
n Unwind the loop twice (in the $x$ direction) 6+1 registers, and
n Interleave two copies of the code (Software-pipelining technique)
n Schedule - it is possible to obtain perfect pairing (without stalls) of this code (not shown)

## Vertical filter summary

n Operating on 4 (not 8) pixels in parallel
n Operating on the original pixels - writing result 2 lines above the original
n This shifts the image but can be compensated elsewhere, e.g. in horizontal filter
n Efficient utilization of processor's L1 cache

## Horizontal filter strategy

n $\left[x 0^{\prime}, x 1^{\prime}, x 2^{\prime}, x 3^{\prime}, x 4^{\prime}, x 5^{\prime}, x 6^{\prime}, x 7^{\prime}\right]=$

$$
\begin{aligned}
& \text { h0 * }[x p, x 0, x 1, x 2, x 3, x 4, x 5, x 6]+ \\
& h 1^{*}[x 0, x 1, x 2, x 3, x 4, x 5, x 6, x 7]+ \\
& h 2^{*}[x 1, x 2, x 3, x 4, x 5, x 6, x 7, x 8]
\end{aligned}
$$

## Synthesis of the sets

n Not everything in memory can be aligned
=>
n $[x 0, x 1, x 2, x 3, x 4, x 5, x 6, x 7]=$ Q1
n $[x p, x 0, x 1, x 2, x 3, x 4, x 5, x 6]=$ (Q0>>56) | (Q1<<8)
n $[x 1, x 2, x 3, x 4, x 5, x 6, x 7, x 8]=$ (Q2<<56) | (Q1>>8)

## Unscheduled code (1)

```
Horizontal pass of a 3x3 separable image filter
Assume:
    esi points to beginning of input line
    edi points to beginnig of output line
    ecx is an offset within the line
    memv0 is the memory location containing [v0,v0,v0,v0] (16 bit values)
    memv1 is the memory location containing [v1,v1,v1,v1] (16 bit values)
    memv2 is the memory location containing [v2,v2,v2,v2] (16 bit values)
    mm6 contains zero
;
mova mmO, [esi + 8* ecx -8] ; Load QO
mova mm1, [esi + 8* ecx] ; Load Q1
mova mm3,mm1
movg mmo, [esi + 8* ecx +8] ; Load Q2

; Write result into memory

```

\section*{Horizontal filter summary}
n 2 sets of input - once to filter low-order 4 pixels, once for the high-order 4 pixels
n It is possible to obtain perfect pairing (without stalls) of the code (not shown)

\section*{Conclusion}
n Image filtering is rewarding topic for MMX optimization
n My current work - extension of these ideas:
1. From 2D (image filtering) to 3D (volume filtering)
2. Bigger kernel \((5 \times 5 \times 5,7 \times 7 \times 7)\)
3. Floating-point calculations
